I created this project to share the warmth and joy that candle making gives me as I begin building my own candle business. This site is not only about the process of making candles, but also my own process as I learn and experiment with it myself.

Candles have always helped me while I work. The soft light eases my mind and helps me focus. I am also drawn to the flame itself and the gentle halo of light it creates around it.

Watching a flame feels calming and almost hypnotic, and I love the small glowing embers that appear inside it. I think they are beautiful. That quiet moment of warmth, light, and embers is what inspired the name of my candle business. This is how Belle Embers was born.

materials

Introduces the ingredients and tools used to make the candles, such as wax, fragrance oils, jars, moulds, and tools like thermometers and scales.

process

Shows the step by step method I use to make my candles, from measuring and melting wax to pouring, curing overnight, and adding decorative mould toppers.

process

Shows the step by step method I use to make my candles, from measuring and melting wax to pouring, curing overnight, and adding decorative mould toppers.

fixes

Explains common candle making problems such as tunneling, frosting, and wet spots, and how they can be improved.

builder

An interactive page where visitors can design their own candle topper layouts before creating one themselves.

materials

These are the main materials and tools used to make Belle Embers candles, from preparing the jars to pouring the wax and adding decorative toppers.

wax

Wax is the base of the candle. For example, 4 candles in 8 oz jars would need about 32 oz of wax.

jars or vessels

Jars hold the candle and affect the final look. Leave a little space at the top if you plan to add mould toppers later.

jars or vessels

Jars hold the candle and affect the final look. Leave a little space at the top if you plan to add mould toppers later.

wicks

Wicks are attached to the jars using sticky tabs or a glue gun. A wick centering tool helps keep them straight while the wax sets.

fragrance oil

Fragrance gives the candle its scent. Around 5% while 7%

process

Making a candle is a slow process. Each step affects the final burn, scent, and surface.

1. measure wax

Measure your wax based on how many candles you are making. For example, four 8 oz candles require 32 oz of wax.

2. melt wax

Melt the wax slowly to around 170°F. Do not overheat. Stir gently so it melts evenly.

3. check temperature

Let the wax cool to around 160°F before adding fragrance. A thermometer is important here.

4. add fragrance

Add 5–7% fragrance oil depending on how strong you want it. Stir for about 2 minutes.

5. add dye (optional)

Add dye if desired and stir the same way as fragrance to fully combine it with the wax.

6. make moulds

Pour wax into moulds like bunnies or hearts. Let them fully cool before removing.

7. final candle

After the candle cures overnight, attach moulds by slightly melting their base and pressing them onto the top.

If you encounter any problems during this process, visit the [fixes page](#) for solutions.

fixes

Candle making does not always go perfectly. Most problems are common, and many can be improved with small adjustments to temperature, pouring, cooling, or wick choice.

tunneling

Tunneling happens when the candle burns down the centre instead of melting across the full top surface. This is often caused by a wick that is too small or by not allowing the candle to burn long enough on the first burn.

frosting

frosting

Frosting appears as pale or white crystal patterns on soy wax. This is natural and does not mean the candle is ruined.

It can often be reduced by pouring at a better temperature and letting the candle cool slowly.

wet spots

Wet spots happen when the wax pulls away from the inside of the jar as it cools.

They are usually caused by temperature changes while cooling. Warming the jars slightly before pouring can help.

sinkholes

Sinkholes can appear near the wick as the wax cools and contracts.

A second small pour or gentle heat can help smooth the surface.

rough tops

Rough or uneven tops often happen when wax cools too quickly or the pour temperature is off.

Slower cooling and more controlled pouring can help create a smoother finish.
